

ReInsight is an interactive analysis tool that gives users the ability to extract the data they need for reporting and decision making from a databank containing an abundance of reinsurance information.

Large volumes of data as well as inconsistent and incompatible systems often get in the way of quick analysis. ReInsight helps you analyze the entire inventory of reinsurance information (e.g. damage and cost ratios) and to display the results in terms of loss reserves, payments, open items or ratings.

Whether for underwriting year, development year, division, assignor, contracts, or damages – the analysis is carried down to the individual posting records using such techniques as settlement triangles, chain ladder methods and the depiction of the involved mandatory or optional businesses.

In addition, ReInsight provides access to information that does not lie directly in the inventory management system, for example, information in Crester Zones and spatial data analysis systems.

ReInsight functions with every inventory management system through the BI-tool QlikView and, in conjunction with netReins, ReInsight has already been successfully implemented.
